

Hyperbaric Physiology

The Rouse Story

- Oct 12, 1992, off the New Jersey coast
- father/son team of experienced divers
- explore submarine wreck in 230 ft (70 m)
- breathing compressed air
- trapped in wreck & escaped with no time for decompression

Chris and Chrissy Rouse

Arrival at recompression facility

- Both divers directly ascend to dive boat
- Helicopter arrives at boat in 1 hr 27 min
- Bronx Municipal Hospital recompression facility
 - Chris (39 yrs) pronounced dead
 - Chrissy (22 yrs)
 - coherent and talking
 - paralysis from chest down
 - no pain
 - blood sample contained foam

Recompression efforts

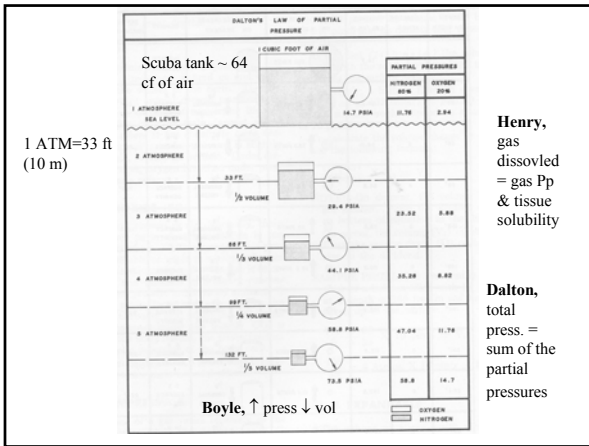

- Recompression starts about 3 hrs after ascent
 - put on pure O₂ and compressed to 60 ft
 - extreme pain as circulation returned
 - compressed to 165 ft, then over 5.5 hrs gradually ascended back to 30 ft., lost consciousness
 - back to 60 ft. Heart failure and death
- autopsy revealed that the heart contained only foam

Medical Debriefing

- Doctors conclusions regarding their treatment
 - nothing short of recompression to extreme depths - 300 to 400 ft
 - saturation treatment lasting several days
 - complete blood transfusion
 - deep helium recompression

Gas Laws

- Boyle's Law
 - $P_1V_1 = P_2V_2$
- Dalton's Law
 - total pressure is the sum of the partial pressures
- Henry's Law
 - the amt of gas dissolved in liquid at any temp is proportional to it's partial pressure and solubility

- ## Gas problems during diving
- Rapture of the deep (Nitrogen narcosis)
 - Oxygen toxicity
 - Hypoxia
 - Contaminated gases
 - Hypercapnia

- ## Martini's Law
- Every fifty feet of depth is approximately equal to drinking one martini on an empty stomach (increased N₂ in tissues)
 - euphoria at > 30m
 - at pressures > 100m, unconsciousness
 - determines a physical limit for breathing air at depth
 - no apparent adaptation in humans
-
- Nitrogen narcosis*

- ## Narcotic gases
- **All Noble gases cause narcosis**
 - outer shell filled with electrons
 - **chemically inert but narcotic properties depend on their solubility in body fat**
 - **mechanism for narcosis is unknown (cell membrane)**
- | INERT GAS | MOLECULAR WEIGHT | OIL/WATER SOLUBILITY | NARCOTIC POTENCY |
|-----------|------------------|----------------------|------------------|
| Hydrogen | 2 | 2.1 | .56 |
| Helium | 4 | 1.7 | .24 |
| Neon | 20 | 2.1 | 0.28 |
| Nitrogen | 28 | 5.2 | 1.0 |
| Argon | 40 | 5.3 | 2.3 |
| Krypton | 84 | 9.6 | 7 |
| Xenon | 131 | 20 | 25 |

- ## Oxygen Toxicity
- Occurs from breathing 100% O₂ too long
 - in 1 ATM, > 12hrs
 - Occurs from pressuring a gas mixture
 - in 7 ATM, > 5 min
 - **Symptoms**
 - coughing, mild irritation under sternum, burning in trachea or bronchi
 - convulsions

- ## High Pressure Nervous Syndrome (HPNS)
- Increasing pressure reverses the effects of narcosis
 - hyper-excitability effect
 - mechanism is also unknown
 - fluidity of membranes, NT release, post-synaptic effects?
 - Forms a barrier to very deep diving
 - HPNS at pressures > 200m

Symptoms of HPNS

- Rapid tremor, poor coordination, involuntary jerking movements, microsleep
- no evidence of adaptation in humans
- addition of narcotic gases decreases the effect and increases max depth
 - Trimix (helium, nitrogen, oxygen)
 - heliox (helium and oxygen)
 - nitrox (air enriched with oxygen)
- HPNS limits the max depth humans can dive

Mixed gases

- Prevents HPNS
- reduces gas density
 - work of breathing increases with depth as gas density increases
 - helium and hydrogen are much less dense than air
 - mixed with O₂ will support ventilation with light work at depths as deep as 1500m
- controls oxygen level (↓O₂ as ↑depth)

Breathe hold diving

- Oldest form of diving
 - 4500 BC artifacts
 - Ama divers
- time limitations
 - usually about 60 s
 - hyperventilation, 4.5 min
 - world record, 7 min 41s
 - hyperven. + O₂, 20.1 min
- risks
 - blackout
 - barotrauma

Hyperbaric injuries

- Lung squeeze (30m or more)
 - TLC < RV
 - fluid is drawn into alveoli
 - alveoli rupture
 - pneumothorax
- Middle ear squeeze
 - affects 40% of divers

Hyperbaric injuries, cont.

- Sinus squeeze (infection and allergies)
- face-mask squeeze (ruptured eye vessels)
- GI barotrauma (chew gum, carbonated fluids, beans)
- Alternobaric vertigo (unequal middle ear pressure)
- Air embolism (failure to breathe out during ascent)
 - has occurred in depths as little as 6 ft

Decompression Sickness

- Caissons used in 1840 to build bridges
 - bends, chokes, staggers (vestibular system)
- Nitrogen forms bubbles during ascent
- occurs after dives > 30m
- symptoms usually appear within 3 hrs of completing the dive
 - joint pain
 - neurological hits, paralysis, confusion
 - skin mottling

DCS Tables history

- Paul Bert--first described DCS
- JS Haldane-- developed first DCS tables
 - descend rapidly, spend limited time on the bottom, ascend slowly to the surface in stages
 - ascend 1/2 way rapidly
 - ascend set amts and stop

Decompression Tables

Depth, ft	Bottom time (min)	Time to first stop (min)	Decompression stops (feet)										Total ascent time (min)	Repeat time (min)								
			110	100	90	80	70	60	50	40	30	20			10							
170	10	2:40														2:00	D					
	15	2:00														2	4:50	F				
	20	2:30														2	2:00	M				
	25	2:30														4	15	21:50	J			
	30	2:30														2	7	29:50	L			
	40	2:30														4	13	20	45:50	M		
	50	2:10														1	10	28	45	81:00	D	
	60	2:00														5	18	23	61	139:00	Z	
	80	2:00														2	18	22	37	74	158:00	Z
180	5	2:50														1	0	2:00	D			
	10	2:40														1	3	8	12:00	L		
	20	2:30														5	17	29:00	K			
	25	2:30														3	10	24	40:00	L		
	30	2:30														6	17	27	53:00	N		
	40	2:30														3	14	23	30	58:00	D	
	50	2:10														2	8	19	32	65	129:00	Z
	60	2:10														5	18	19	44	81	168:00	Z
190	5	2:50														1	0	3:10	D			
	10	2:00														4	7	7:10	D			
	20	2:40														2	6	20	31:10	K		
	25	2:40														5	11	26	44:10	M		
	30	2:30														1	9	19	43	63:10	N	
	40	2:00														4	14	28	59	105:10	D	

Dysbaric Osteonecrosis

- Divers with a history of DCS
- 20% in divers who work below 200m
- bubbles reduce capillary flow to bone and cause bone cells to die
- damage mainly in the end of long bones

Open Circuit Scuba Gear

- Air is fed with a demand regulator at ambient pressure
- air is exhaled to the water forming bubbles

Jacques Cousteau and Emile Gagnan developed the demand valve in 1943

Closed Circuit Scuba Gear

- Air is fed to the diver with a demand regulator at ambient pressure
- 100% O₂ is recycled through a CO₂ scrubber
- depth is limited
 - to < 8m for pure O₂
 - to < 25m with 60% O₂, 40% air
 - must purge nitrogen periodically
- No bubbles

Carbon Dioxide Toxicity

- Occurs with closed systems
 - diving for > 4-6 hrs
 - headache is usually the critical first warning
- Occurs at depth due to pressure
 - First described by JBS Haldane
 - Br sub Thetis sunk in 1939, 99 men died only 4 escaped
 - small escape chamber where men exhaled and CO₂ increased to 6%
 - when escape pressure was pressurized to 10 ATM, CO₂ effect became fatal

CO₂ symptoms

Table 4.3
Signs and Symptoms of Acute Exposure to Elevated Carbon Dioxide Levels in Normal Men

CO ₂ percent of inhaled gas*	Effects of exposure
0-4	No CNS derangement
4-6	Breathlessness, anxiety
6-10	Impaired mental capabilities
10-15	Severely impaired mental function
15-20	Loss of consciousness
>20	Muscular twitching, convulsions

* At sea level. At great depths, the effects of these CO₂ levels will be magnified.
Adapted from Clark and Thom 1997.

Cardiac arrhythmias

- Common during diving even in young divers
 - 22 x more arrhythmias when submerged
- Why?
 - blood pressure increase with breathe hold
 - pressure from wet suit on the carotid sinus
 - fatigue, dehydration, cold
 - increased central blood volume

Drowning

- A Perfect Storm pgs 179-186
- A graphic description of what it feels like to drown
 - based on report by James Lowson 1892
 - shipwreck survivor
- stages of drowning
 - struggling to hold breath
 - must breathe, water triggers laryngeal spasm
 - pain recedes, euphoric feeling, final thoughts
 - unconsciousness

Susceptible Populations for DCS

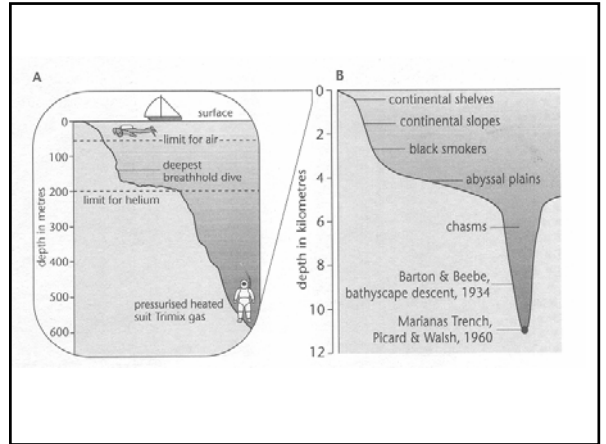

- Females?
 - Greater body fat (↑ nitrogen dissolved in fat)?
 - increased symptoms during menstruation
 - don't dive when pregnant!
- Age effect
 - > in middle-aged than younger men
- Foramen Ovale
 - inadequate closure of hole between right and left atria in 25% of people
 - bubbles may occur in the cerebral circulation

Other precautions

- Avoid dehydration
- no strenuous exercise 6 hrs after diving
- do not fly for at least 12-24 hrs after diving
- increase decompression time when diving at altitude

Limits

- 30m, nitrogen narcosis (limit for air)
- 30 - 200m, oxygen toxicity and increased work of breathing (breathe mixed gases)
- > 200m HPNS, breathe trimix gas
- 450m, limit for open sea diving
- 600m, limit with pressure chamber

Saturation Diving

- **Live and work at depths up to about 300m to avoid lengthy decompression**
 - breathe heliox
 - following 100m, 4 d decompression
 - following 300m, 10 d decompression
- **helium speech unscrambler**
- **30°C living quarters**

Tektite II 1970

The abyss

- **Abyssal plains**
- **need pressure-resistant vessels**
 - 1620, first submarine (Cornelius Drebbel)
 - 1934, bathysphere, William Beebe and Otis Barton
 - 1940, bathyscaphe, Auguste Piccard
 - 1960, Trieste lands in Mariana Trench

1985 Alvin discovers the Titanic
